

# Lecture 12: Equilibrium Refinements for Extensive Form Games

Extensive form games have many many Nash-equilibria, some not plausible ("incredible threats")

Example: figure 3.14

# 1. Subgame Perfection

Definition: A subgame  $G$  of an extensive form game  $T$  consists of a single node  $x$  and all its successors in  $T$ , with the property that if  $x \in G$  and  $x' \in h(x)$ , then  $x' \in G$ .  $x$  and  $x'$  are in the same information set in  $G$  iff they are in the same information set in  $T$ . The payoff-function of  $G$  is the restriction of the original payoff-function of  $T$  to those terminal nodes belonging to  $G$ .

Example: Stackelberg and Cournot game

Note: Every extensive form game is a subgame of itself.

Let  $\sigma_i$  be a behavior strategy of  $T$ , and let  $\hat{H}$  be the set of information sets belonging to a subgame  $G$ . Then the restriction of  $\sigma_i$  to  $G$  is  $\hat{\sigma}_i$  with  $\hat{\sigma}_i(\cdot | h_i) = \sigma_i(\cdot | h_i)$  for all  $h_i \in \hat{H}$ .

Definition: A behavior strategy profile  $\sigma$  is subgame perfect, if the restriction of  $\sigma$  to any subgame  $G$  is a Nash-equilibrium of  $G$  for every subgame.

Every subgame perfect equilibrium is a Nash equilibrium, but not the other way round

Theorem: Every finite extensive form game has at least one subgame perfect equilibrium.

"Proof" (Application of backward induction): For any terminal node, take the subgame which contains this terminal node, and which does not contain any "smaller" subgame. Calculate the Nash-equilibria of these subgames, and create a new game by replacing each subgame by the payoffs of one of the Nash-equilibria of this subgame. For this new game, take for any terminal node the "smallest" subgame containing the terminal node, etc. Since the game is finite, this process comes to an end after finite steps. The strategy combination consisting of the Nash-equilibrium profiles of all subgames is obviously subgame perfect.

Backward induction: only feasible for finite games

## 2. Problems with Subgame Perfection

Rationality after unexpected moves

Example: Centipede game figure 9.B.8

Survival of unplausible equilibria

Example: Another market entry game figure 9.C.1.

To deal with second problem: Explicit specification of beliefs at information sets with more than one node.

### 3. Beliefs

Denote by  $i_h$  the player controlling information set  $h$ .

Definition: A system of beliefs  $\mu$  for an extensive form game  $\Gamma$  is a specification of a probabilities  $\mu(x) \in [0, 1]$  for each  $x$  in  $\Gamma$  such that

$$\sum_{x \in h} \mu(x) = 1$$

for all  $h \in H$ .

For each information set  $h$  the belief system  $\mu$  specifies a probability distribution over the nodes  $x$  belonging to  $h$ .

Interpretation: For each info set  $h$  the belief system  $\mu$  specifies the belief of player  $i_h$  at which node within the info set he is when  $h$  is actually reached.

Whenever  $h$  consists of only one node, there is trivially only one belief possible.

## 4. Perfect Bayesian Equilibrium

Definition: A belief system  $\mu$  is consistent with a strategy profile  $b$  if it holds for all  $x$ ,  $x \in h_x$ , that

$$\mu(x) = \frac{\text{prob}(x | b)}{\text{prob}(h_x | b)}$$

whenever  $\text{prob}(h_x | b) > 0$ .

"Whenever the strategy profile  $b$  does not exclude that a particular info set  $h_x$  is reached, the belief of the player  $i_{h_x}$  is consistent with Bayesian updating".

Recall:  $\text{prob}(h | b) = \sum_{x \in h} \text{prob}(x | b)$

Definition: A strategy profile  $b$  is sequentially rational with respect to a belief system  $\mu$  if for all information sets  $h \in H$  the following holds:

$$E[u_{i_h} | h, \mu, b_{i_h}, b_{-i_h}] \geq E[u_{i_h} | h, \mu, \tilde{b}_{i_h}, b_{-i_h}]$$

for all  $\tilde{b}_{i_h} \in B_{i_h}$  that allow to reach  $h$ .

"Given that info set  $h$  is reached, given player  $i_h$ 's belief about where in the info set he is, and given what the other players are doing, player  $i_h$ 's choice at  $h$  maximizes his expected payoff."

Definition: A strategy profile  $b$  and a belief system  $\mu$  form a Perfect Bayesian Equilibrium (PBE) if:

- i)  $\mu$  is consistent with  $b$ , and
- ii)  $b$  is sequentially rational with respect to  $\mu$ .

But: Depending on the application, PBE is sometimes too weak - does not respect subgame perfection.

Example: Figure 9.C.5

Problem: No restrictions on beliefs of info sets that should not be reached  
 $\implies$   
sometimes stronger requirements on the beliefs needed.

## 5. Sequential Equilibrium

If  $b_m$  is a completely mixed strategy profile, all info sets are reached with positive probability  $\Rightarrow$

unique belief profile  $\mu$  that is consistent with  $b_m$ , denoted by  $\mu(b_m)$ .

Let  $\{b_m^k\}$  be a converging sequence of completely mixed strategy profiles with  $\lim_{k \rightarrow \infty} b_m^k = \bar{b}$ .

Take the limit of the belief profiles consistent with the  $\{b_m^k\}$ ,  $\lim_{k \rightarrow \infty} \mu(b_m^k) = \bar{\mu}$ .  $\bar{\mu}$  is unique and consistent with  $\bar{b}$ .

Definition: A strategy profile  $b$  and a belief system  $\mu$  form a Sequential Equilibrium if:

- i)  $b$  is sequentially rational with respect to  $\mu$ .
- ii) There exists a sequence of completely mixed strategy profiles  $\{b_m^k\}$  such that  $\lim_{k \rightarrow \infty} b_m^k = b$  and  $\lim_{k \rightarrow \infty} \mu(b_m^k) = \mu$ .
